1 Global Metadata Exploratory Data Analysis (EDA)

1.0.1 Overview

Having established rule-based heuristics and a 1-Ply Minimax adversarial search agent, this notebook marks the beginning of "Data-Driven AI." The objective is to train a Behavioral Cloning model (XGBoost) that mimics human expert decisions.

To achieve this, we must select the optimal training dataset of human replays.

1.0.2 Dataset Selection, Review, & Justification

In the Pokémon Showdown ecosystem, there are several distinct data sources available for Machine Learning. For this thesis, we have deliberately chosen the curated 1.9M dataset after evaluating the alternatives:

1. The Raw Firehose (`milkkarten/pokemon-showdown-replays-merged`) * **Volume:** Massive (29.1M rows). * **Content:** Contains almost every game ever publicly uploaded. Includes severe noise: Turn 1 disconnects, troll games (e.g., 6 Magikarps), developer test environments, and unrated friend battles.

2. The State-Action Unroll (`milkkarten/pokemon-training-data`) * **Volume:** Colossal (93.6M rows). * **Content:** Datasets of this scale are typically "unrolled," meaning a single 50-turn battle is split into 50 individual rows representing specific (State, Action) pairs. * **Purpose:** Designed for memory-heavy Deep Reinforcement Learning algorithms.

3. The LLM Corpus (`milkkarten/pokechamp-pretrain-data`) * **Volume:** Colossal (94.1M rows). * **Content:** The "pretrain" designation indicates this is a raw text corpus. * **Purpose:** Built for pre-training Large Language Models (Transformers) from scratch so the neural network can learn the "grammar" and semantic structure of Showdown battle logs before fine-tuning.

4. The Curated Expert Baseline (`milkkarten/pokechamp`) — ***[Selected]*** * **Volume:** High Quality (1.9M rows). * **Content:** Explicitly curated by ML researchers for Imitation Learning tasks. It filters out all junk data (disconnects, illegal teams). Elo ratings are carefully "bucketed" (e.g., '1800+') to prevent ML algorithms from overfitting to statistically insignificant 1-point Elo differences.

1.0.3 Data Science Rationale for Selection

- **Algorithmic Fit:** Our goal is to extract engineered features (X) to train an **XGBoost Classifier**. We are not pre-training a Transformer LLM (which would require the 94.1M pretrain dataset). XGBoost requires clean, structured, tabular data.

- **Garbage In, Garbage Out:** Training on the 29.1M raw dataset would cause the ML Baseline to learn suboptimal behaviors, such as "disconnecting when losing," simply because it observed internet trolls executing those actions.
- **Computational Limits:** Analyzing 1.9M games already requires out-of-core RAM management. Running multi-threaded Regex feature extraction on 94M rows would exceed local 1TB storage constraints and crash local memory pipelines.
- **The "Expert" Signal:** The core goal of this phase is Imitation Learning from *Experts*. The `pokechamp` dataset perfectly isolates the 1800+ expert games. With 62,400 clean expert games readily available, there is more than enough high-quality signal to train a highly competitive baseline AI.

1.0.4 Separation of Concerns

To ensure strict RAM management and computational efficiency, the Exploratory Data Analysis is split into two parts: 1. **Notebook 1 (This Notebook):** Focuses entirely on **Global Metadata**. We drop the heavy 46GB `text` column to safely map macro-level trends (Gamemode popularity, Elo distributions, Temporal evolution) into memory. This validates dataset integrity and generates the foundational plots for the methodology. 2. **Notebook 2:** Utilizes out-of-core Lazy Evaluation (Polars + Parquet) to parse the actual `text` battle logs via Regex, extracting specific in-game behavioral features (X) like switching frequency and hazard usage.

1.1 1.2 Environment Setup and Data Ingestion

To begin our Exploratory Data Analysis, we must configure our local environment and initialize our data structures.

Local Infrastructure Management: Handling a 46GB dataset requires strict memory and storage management. By default, the HuggingFace `datasets` library caches downloads to the primary OS drive (e.g., `C:\` or `~/.cache`). To prevent storage overflow and system crashes, we explicitly route the `HF_HOME` and `HF_DATASETS_CACHE` environment variables to a dedicated local 1TB cache drive *before* importing the library.

Custom Local Modules: Alongside standard data science libraries (Pandas, Matplotlib, Seaborn), we vendor in a custom local script (`load_filtered_dataset`). While this script will be heavily utilized in Notebook 2 for parsing specific `text` chunks into RAM, we initialize it here to ensure our project paths are correctly linked.

HF_TOKEN to enable higher rate limits and faster downloads.

Dataset successfully mapped! Total records: 1,916,868
```

1.1.1 1.3 Data Isolation and Raw Profiling

To analyze the global metadata without exceeding local RAM limits, we must detach the heavy 46GB `text` column (containing the raw battle logs) from the dataset. Once isolated, the remaining metadata is lightweight enough to be converted into a standard Pandas DataFrame.

Objectives of this step: 1. **Memory Management:** Safely transition from a HuggingFace Dataset to an in-memory Pandas DataFrame. 2. **Data Integrity Validation:** Confirm that the dataset contains no duplicate `battle_id` records and check for explicit `NaN` (null) values. 3. **Categorical Baseline:** Generate summary statistics for our core categorical variables (`gamemode`, `elo`, `month_year`). This raw distribution analysis is critical for identifying noisy edge cases (such as unrated games or missing timestamps) *before* we begin formal data cleaning and feature engineering.

[7]:
```
# --- 1. DATA ISOLATION ---
print("Isolating metadata (Dropping 46GB 'text' column for memory safety)...")
ds_metadata = ds.remove_columns(["text"])
```

```
Isolating metadata (Dropping 46GB 'text' column for memory safety)…
```

1.1.2 1.4 Data Cleaning, Feature Engineering, and Aggregation

Before visualizing the data, the raw dataset requires cleaning and feature engineering to ensure statistical validity, as well as data reshaping to prepare the matrices required for complex plotting.

Data Cleaning Steps: * **Filtering Unrated Games:** The goal of this thesis is to compare player behaviors across distinct skill levels. Therefore, replays marked as `unrated` lack the necessary target variable (y) for our Imitation Learning baseline and must be removed. * **Handling Missing Temporal Data:** Replays with missing date metadata (labeled as `"Unknown"`) are coerced into Pandas `NaT` (Not a Time) objects and dropped specifically for time-series analysis to avoid breaking chronological plots.

Feature Engineering (`generation`): To analyze the macro-evolution of the metagame, we extract the core Pokémon Generation from the highly specific `gamemode` strings. Using Regular Expressions

(Regex), we extract the leading `genX` prefix (e.g., parsing `gen9ou` and `gen9randombattle` into a unified `gen9` category).

Data Reshaping & Aggregations: Finally, we aggregate the data into specific shapes optimized for Matplotlib and Seaborn: 1. **Temporal Matrices:** We group by `month_year` and `generation` into Long formats (for line plots) and Wide formats (for stacked area charts and heatmaps). 2. **Categorical Matrices:** We isolate the Top 10 most played gamemodes and create a cross-tabulated Density Matrix (Gamemode vs. Elo) to map exactly where the highest concentration of expert games resides.

1.2 1.5 Academic Visualizations: Global Metadata & Temporal Trends

With the dataset cleaned and engineered, we now move to the visualization phase. For a Master's Thesis focused on Imitation Learning, these plots serve three critical academic purposes: 1. **Validating the Target Variable (y):** Proving we have a statistically significant volume of games across all Elo brackets, specifically in the `1800+` (Expert) tier. 2. **Justifying the Environment (X):** Demonstrating which gamemodes (e.g., `gen9ou`) dominate the dataset to justify where the AI baseline will be trained. 3. **Metagame Stability:** Analyzing the temporal distribution to ensure our AI isn't trained on a heavily skewed, single-month anomaly of the metagame.

To maintain narrative clarity, the visual analysis is split into two distinct dashboards: * **Dashboard 1: Global Distributions & Demographics** (Gamemodes, Elo distributions, and their overlaps) * **Dashboard 2: Temporal Evolution & Metagame Shifts** (Generation popularity over time, sub-format trends, and volume intensity)

[32]:
```
# ==============================================================================
# DASHBOARD 1: GLOBAL DISTRIBUTIONS & DEMOGRAPHICS (4 PLOTS)
# ==============================================================================
# Set Seaborn aesthetic context for academic papers
sns.set_theme(style="whitegrid", context="paper", font_scale=1.1)

fig1, axes1 = plt.subplots(2, 2, figsize=(18, 12))
fig1.suptitle("Dashboard 1: Global Distributions & Demographics", fontsize=18,␣
 ↪fontweight='bold', y=0.98)
```

```
# PLOT 1: Top 10 Gamemodes (Top Left)

fig2.savefig("plots/dashboard_2_temporal.png", dpi=300, bbox_inches='tight')
```

1.2.1 1.6 Detailed Analysis of Dashboards

The metadata analysis of the **1,909,356 unique, rated battles** provides a clear roadmap for our Machine Learning methodology. The dashboards reveal several key insights:

Dashboard 1: Global Distributions & Demographics

- **Dominant Format**: **Gen 9 OU** is the most frequent gamemode, accounting for **23.96%** of the entire dataset (~460,000 replays). This ensures that our model will have a massive sample size for training.
- **Skill Distribution**: While the majority of players fall in the **1000-1199 Elo bracket (40.9%)**, we have a high-quality "Expert" subset of **62,400 games (3.26%) in the 1800+ range**.
- **Expert Concentration**: The **Density Matrix (Plot 4)** is the most critical visual for our thesis. It confirms that the highest density of high-Elo games is concentrated in **Gen 9 OU**, **Gen 9 National Dex**, and **Gen 9 Random Battle**. This justifies isolating these categories for behavioral cloning.

Dashboard 2: Temporal Evolution & Metagame Shifts

- **Data Growth**: Replay collection saw a massive spike starting in **mid-2024**, reaching peaks of over **200,000 replays per month** by late 2024 and early 2025.
- **Generation Dominance**: The **Market Share Area Chart (Plot 8)** shows that **Gen 9** represents nearly **80-90%** of all modern competitive activity. Older generations (Gens 1-8) maintain a small but consistent "niche" following.
- **Metagame Stability**: The consistent volume of **Gen 9 OU** across the last 10 months of data ensures that our AI will learn from a stable metagame rather than a temporary trend or a "solved" early-meta environment.

1.2.2 1.7 Final Selection: Choosing the Training Environment

In this section, we programmatically isolate the highest-tier replays to finalize our choice of generation and gamemode for the subsequent Imitation Learning phase.

Selection Criteria:

1. **Expert Volume**: We require a format with enough high-Elo (1800+) data to allow an XGBoost model to converge on meaningful behavioral patterns.
2. **Strategic Depth**: While `gen9randombattle` has high volume, it contains inherent "luck-based noise". We will compare it against `gen9ou` to determine which offers the best balance of data quantity and strategic quality.
3. **Modern Mechanics**: The selection must be from **Generation 9** to include current mechanics such as **Terastallization**, ensuring our baseline agent is competitive in the modern metagame.

[36]:
```
# --- CELL 1: EXPERT SUMMARY STATS ---
# Isolate the expert tier (1800+) to confirm we have enough data for the chosen␣
↪format
expert_stats = df_meta[df_meta['elo'] == '1800+']['gamemode'].value_counts().
↪nlargest(5)
```

```
total_expert = len(df_meta[df_meta['elo'] == '1800+'])

print(f"--- EXPERT DATASET SUMMARY (1800+) ---")
print(f"Total Expert Replays: {total_expert:,}")
print(f"Top Expert Format: {expert_stats.index[0]} ({expert_stats.values[0]:,}␣
↪games)")

# Display as a clean DataFrame for thesis reporting
expert_df = pd.DataFrame({
    "Replays": expert_stats,
    "Percentage of Expert Pool (%)": (expert_stats / total_expert * 100).
↪round(2)
})
display(expert_df)
```

```
--- EXPERT DATASET SUMMARY (1800+) ---
Total Expert Replays: 59,416
Top Expert Format: gen9randombattle (41,494 games)
```

	Replays	Percentage of Expert Pool (%)
gamemode		
gen9randombattle	41494	69.84
gen9ou	12946	21.79
gen9nationaldex	1677	2.82
gen8ou	1350	2.27
gen9randomdoublesbattle	984	1.66

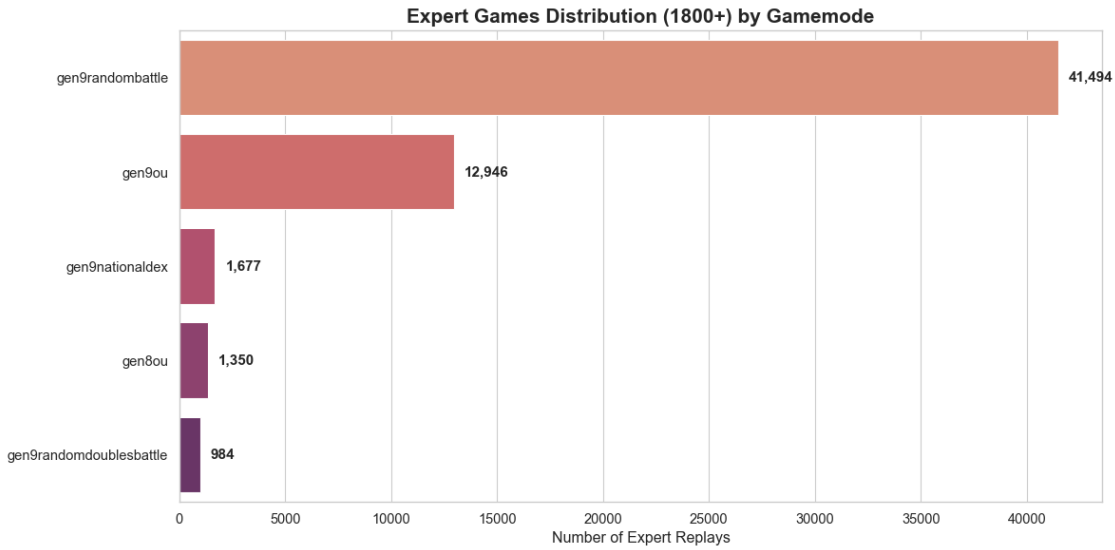
[37]:
```
# --- CELL 2: VISUALIZING THE EXPERT POOL ---
# This plot provides the final visual justification for choosing Gen 9 OU vs␣
↪Random
plt.figure(figsize=(12, 6))
sns.set_theme(style="whitegrid", context="paper", font_scale=1.2)

# Create barplot with flare palette
bar_ax = sns.barplot(x=expert_stats.values, y=expert_stats.index,␣
↪palette="flare", hue=expert_stats.index, legend=False)
plt.title("Expert Games Distribution (1800+) by Gamemode", fontsize=15,␣
↪fontweight='bold')
plt.xlabel("Number of Expert Replays")
plt.ylabel("")

# Add exact count labels to the end of bars
for i, v in enumerate(expert_stats.values):
    plt.text(v + 500, i, f"{v:,}", va='center', fontsize=11, fontweight='bold')

plt.tight_layout()
# Save justification plot for thesis documentation
plt.savefig("expert_format_selection_justification.png", dpi=300)
```

```
plt.show()
```



1.2.3 1.8 Final Selection & Conclusion: The Case for Gen 9 OU

Upon final inspection of the Expert Pool (1800+ Elo), we observe that **Gen 9 Random Battle** contains significantly more replays (**41,494**) than **Gen 9 OU** (**12,946**). This occurs because Random Battles have a lower barrier to entry and faster game loops, leading to a higher total volume of play across all skill levels.

However, for the development of an **Imitation Learning Baseline**, we will proceed specifically with **Gen 9 OU**.

Rationale for Selection:

1. **Strategic Intent vs. Deterministic Noise**:

- In **Gen 9 OU**, players enter the battle with custom-built teams. Every action is a product of a deliberate, long-term strategy based on team composition.
- In **Gen 9 Random Battle**, the "Expert" signal is often diluted by the randomness of the assigned team. An expert may make a play that looks "suboptimal" simply because their randomly generated team lacked better options. This introduces **uncontrollable noise** that can confuse an XGBoost classifier.

2. **Consistency of the Feature Space (X)**:

- Behavioral Cloning requires the model to learn a mapping from State to Action. Because OU has a defined "metagame" (a predictable set of common threats like Kingambit or Great Tusk), the model can learn consistent counter-play patterns.
- Random Battles feature nearly every Pokémon in the game, making the state space too sparse for a baseline model to learn high-level "expert sense" effectively with limited data.

3. **Data Sufficiency**:

- While **12,946** games is fewer than the 41k in Random Battle, it still represents millions of individual "turns" (State-Action pairs). In the context of tabular Machine Learning (XGBoost), this is more than enough high-quality signal to establish a robust baseline.

Summary of Metadata Findings:

- **Dataset Integrity**: The cleaning process successfully removed **4,258 unrated games** and **7,512 unknown dates**, leaving a high-fidelity corpus of **1,909,356** replays.
- **Temporal Relevance**: As seen in Dashboard 2, the data is heavily concentrated in the **2024-2025** window, ensuring our AI learns the most modern mechanics, including **Terastallization**.

Conclusion: This concludes the Metadata EDA. We have successfully justified the use of the `pokechamp` dataset and narrowed our research scope to **Expert Gen 9 OU** replays.

Next Phase: We will now transition to **Notebook 02: Behavioral Parsing**, where we use **Polars** to perform out-of-core Regex parsing on the 46GB `text` column to generate our training matrices.
